Lexical statistics & word frequency distributions

Lexical statistics

Zipf (1949, 1965); Baayen (2001); Baroni (2008)

- ► Statistical study of the frequency distribution of types (words or other linguistic units) in texts
 - remember the distinction between types and tokens?
- ▶ Different from other categorical data because of the extremely large number of distinct types
 - ▶ people often speak of **Zipf's law** in this context
- ► Key applications: productivity and vocabulary richness
 - prevalence of low-frequency types
 - vocabulary growth for incremental samples

Lexical statistics & word frequency distributions

Basic terminology

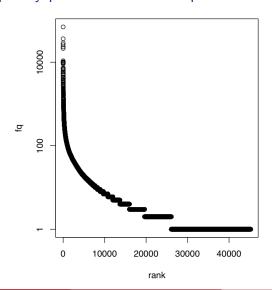

- ► N: sample / corpus size, number of tokens in the sample
- ► V: vocabulary size, number of distinct types in the sample
- \triangleright V_m : spectrum element m, number of types in the sample with frequency m (i.e. exactly m occurrences)
- \triangleright V_1 : number of hapax legomena, types that occur only once in the sample (for hapaxes, #types = #tokens)
- ▶ A sample: a b b c a a b a
- $ightharpoonup N = 8, V = 3, V_1 = 1$

SIGIL (Baroni & Evert)

sigil.r-forge.r-project.org

Lexical statistics & word frequency distributions Basic notions of lexical statistics

Rank/frequency profile of Brown corpus

Rank / frequency profile

- ▶ The sample: c a a b c c a c d
- ► Frequency list ordered by decreasing frequency

▶ Rank / frequency profile: ranks instead of type labels

r	f
1	4
2	3
3	1
4	1

 \blacktriangleright Expresses type frequency f_r as function of rank r of a type

Lexical statistics & word frequency distributions Basic notions of lexical statistics

Top and bottom ranks in the Brown corpus

Typical frequency patterns

Across text types & languages

Lexical statistics & word frequency distributions Typical frequency distribution patterns

Is there a general law?

- ► Language after language, corpus after corpus, linguistic type after linguistic type, ... we observe the same "few giants, many dwarves" pattern
- ► Similarity of plots suggests that relation between rank and frequency could be captured by a general law
- ▶ Nature of this relation becomes clearer if we plot log f as a function of $\log r$

sigil.r-forge.r-project.org

Lexical statistics & word frequency distributions Zipf's law

Zipf's law

Logarithmic version

► Zipf's power law:

$$f(w) = \frac{C}{r(w)^a}$$

▶ If we take logarithm of both sides, we obtain:

$$\underbrace{\log f(w)}_{y} = \log C - a \cdot \underbrace{\log r(w)}_{x}$$

- ► Zipf's law predicts that rank / frequency profiles are straight lines in double logarithmic space
- ▶ Provides intuitive interpretation of *a* and *C*:
 - ► a is **slope** determining how fast log frequency decreases
 - ▶ log C is **intercept**, i.e., predicted log frequency of word with rank 1 (log rank 0) = most frequent word

Zipf's law

- ► Straight line in double-logarithmic space corresponds to power law for original variables
- ▶ This leads to Zipf's (1949; 1965) famous law:

$$f(w) = \frac{C}{r(w)^a}$$

- ▶ With a = 1 and C = 60,000, Zipf's law predicts that:
 - ▶ most frequent word occurs 60,000 times
 - second most frequent word occurs 30,000 times
 - ▶ third most frequent word occurs 20,000 times
 - ▶ and there is a long tail of 80,000 words with frequencies between 1.5 and 0.5 occurrences(!)

Lexical statistics & word frequency distributions Zipf's law

Zipf-Mandelbrot law Mandelbrot (1953, 1962)

Mandelbrot's extra parameter:

$$f(w) = \frac{C}{(r(w) + b)^a}$$

- ightharpoonup Zipf's law is special case with b=0
- Assuming a = 1, C = 60,000, b = 1:
 - ► For word with rank 1, Zipf's law predicts frequency of 60,000; Mandelbrot's variation predicts frequency of 30,000
 - ► For word with rank 1,000, Zipf's law predicts frequency of 60; Mandelbrot's variation predicts frequency of 59.94
- ► Zipf-Mandelbrot law forms basis of statistical LNRE models
 - > ZM law derived mathematically as limiting distribution of vocabulary generated by a character-level Markov process

Some applications

ZM & fZM

Lexical statistics & word frequency distributions Zipf's law

Zipf-Mandelbrot vs. Zipf's law

Non-linear least-squares fit (Brown corpus)

Lexical statistics & word frequency distributions Some applications

Applications of word frequency distributions

- ▶ Application 1: extrapolation of vocabulary size and frequency spectrum to larger sample sizes
 - morphological productivity (e.g. Lüdeling and Evert 2005)
 - ▶ lexical richness in stylometry (Efron and Thisted 1976), language acquisition, clinical linguistics (Garrard et al. 2005)
 - language technology (estimate proportion of OOV words, unseen grammar rules, typos, ...)
- need method for predicting vocab. growth on unseen data
- ► Application 2: Zipfian frequency distribution across types
 - \blacktriangleright measures of lexical richness based on population (\neq sample)
 - population model for Good-Turing smoothing (Good 1953; Gale and Sampson 1995)
 - realistic prior for Bayesian language modelling
- need model of type probability distribution in the population

Statistical LNRE Models

LNRE models for word frequency distributions

- ► LNRE = large number of rare events (cf. Baayen 2001)
- ► Statistics: corpus as random sample from **population**
 - ightharpoonup population characterised by vocabulary of **types** w_k with occurrence probabilities π_k
 - ► not interested in specific types → arrange by decreasing probability: $\pi_1 \geq \pi_2 \geq \pi_3 \geq \cdots$
 - ▶ NB: not necessarily identical to Zipf ranking in sample!
- ▶ LNRE model = population model for type probabilities, i.e. a function $k \mapsto \pi_k$ (with small number of parameters)
 - \blacktriangleright type probabilities π_k cannot be estimated reliably from a corpus, but parameters of LNRE model can
- Parametric statistical model

Statistical LNRE Models

Examples of population models

5. WFD & zipfR

Statistical LNRE Models ZM & fZM

The Zipf-Mandelbrot law as a population model

What is the right family of models for lexical frequency distributions?

- ▶ We have already seen that the Zipf-Mandelbrot law captures the distribution of observed frequencies very well
- ▶ Re-phrase the law for type probabilities:

$$\pi_k := \frac{C}{(k+b)^a}$$

- ▶ Two free parameters: a > 1 and $b \ge 0$
- C is not a parameter but a normalization constant, needed to ensure that $\sum_{k} \pi_{k} = 1$
- ► This is the **Zipf-Mandelbrot** population model

Statistical LNRE Models ZM & fZM

The finite Zipf-Mandelbrot model

- ► Zipf-Mandelbrot population model characterizes an *infinite* type population: there is no upper bound on k, and the type probabilities π_k can become arbitrarily small
- \rightarrow $\pi=10^{-6}$ (once every million words), $\pi=10^{-9}$ (once every billion words), $\pi = 10^{-15}$ (once on the entire Internet), $\pi = 10^{-100}$ (once in the universe?)
- ► Alternative: finite (but often very large) number of types in the population
- ► We call this the population vocabulary size S (and write $S = \infty$ for an infinite type population)

SIGIL (Baroni & Evert)

sigil.r-forge.r-project.org

The finite Zipf-Mandelbrot model

- ▶ The finite Zipf-Mandelbrot model simply stops after the first S types (w_1, \ldots, w_S)
- ▶ S becomes a new parameter of the model \rightarrow the finite Zipf-Mandelbrot model has 3 parameters

Statistical LNRE Models ZM & fZM

Sampling from a LNRE model

Statistical LNRE Models Sampling from a LNRE model

Sampling from a population model

Assume we believe that the population we are interested in can be described by a Zipf-Mandelbrot model:

Use computer simulation to sample from this model:

- ▶ Draw *N* tokens from the population such that in each step, type w_k has probability π_k to be picked
- ▶ This allows us to make predictions for samples (= corpora) of arbitrary size $N \rightarrow \text{extrapolation}$

Random variation: vocabulary growth curve

Statistical LNRE Models Great expectations

Expected values

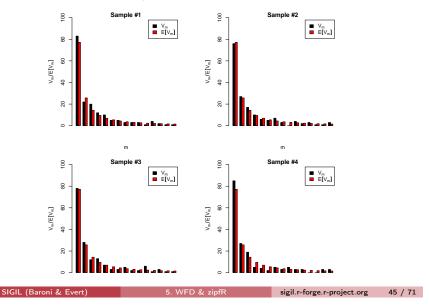

- ▶ There is no reason why we should choose a particular sample to make a prediction for the real data - each one is equally likely or unlikely
- ▶ Take the average over a large number of samples, called expected value or expectation in statistics
- ▶ Notation: E[V(N)] and $E[V_m(N)]$
 - ▶ indicates that we are referring to expected values for a sample
 - ightharpoonup rather than to the specific values V and V_m observed in a particular sample or a real-world data set
- ► Expected values can be calculated efficiently *without* generating thousands of random samples

- ▶ Automatic estimation procedure: a = 2.39 and b = 1968

SIGIL (Baroni & Evert)

Statistical LNRE Models Reliability

Goodness-of-fit

- ► Goodness-of-fit statistics measure how well the model has been fitted to the observed training data
- ► Compare observed vs. expected frequency distribution
 - ▶ frequency spectrum (→ easier)
 - vocabulary growth curve
- Similarity measures
 - ▶ mean square error (→ dominated by large V / V_m)
 - \blacktriangleright multivariate chi-squared statistic X^2 takes sampling variation (and covariance of spectrum elements) into account
- ► Multivariate chi-squared test for goodness-of-fit
 - $ightharpoonup H_0$: observed data = sample from LNRE model (i.e. fitted LNRE model describes the true population)
 - p-value derived from X^2 statistic ($X^2 \sim \chi_{df}$ under H_0)
 - ▶ in previous example: $p \approx 0$:-(

Statistical LNRE Models

Reliability

Outline

Statistical LNRE Models

ZM & fZM Sampling from a LNRE model

Reliability

Statistical LNRE Models Reliability

How reliable are the fitted models?

Three potential issues:

- 1. Model assumptions \neq population (e.g. distribution does not follow a Zipf-Mandelbrot law)
 - model cannot be adequate, regardless of parameter settings
- 2. Parameter estimation unsuccessful (i.e. suboptimal goodness-of-fit to training data)
 - optimization algorithm trapped in local minimum
 - can result in highly inaccurate model
- 3. Uncertainty due to sampling variation
 - (i.e. observed training data differ from population distribution)
 - model fitted to training data, may not reflect true population
 - another training sample would have led to different parameters

SIGIL (Baroni & Evert) sigil.r-forge.r-project.org sigil.r-forge.r-project.org Statistical LNRE Models

Reliability

Statistical LNRE Models

Reliability

Bootstrapping

- ► An empirical approach to sampling variation:
 - ▶ take many random samples from the same population
 - estimate LNRE model from each sample
 - ▶ analyse distribution of model parameters, goodness-of-fit, etc. (mean, median, s.d., boxplot, histogram, ...)
 - problem: how to obtain the additional samples?
- ▶ Bootstrapping (Efron 1979)
 - ► resample from observed data with replacement
 - ▶ this approach is not suitable for type-token distributions (resamples underestimate vocabulary size V!)
- ► Parametric bootstrapping
 - ▶ use fitted model to generate samples, i.e. sample from the population described by the model
 - ▶ advantage: "correct" parameter values are known

Statistical LNRE Models Reliability

Summary

LNRE modelling in a nutshell:

- 1. Compile observed frequency spectrum (and vocabulary growth curves) for a given corpus or data set
- 2. Estimate parameters of LNRE model by matching observed and expected frequency spectrum
- 3. Evaluate goodness-of-fit on spectrum (Baayen 2001) or by testing extrapolation accuracy (Baroni and Evert 2007)
 - ▶ in principle, you should only go on if model gives a plausible explanation of the observed data!
- 4. Use LNRE model to compute expected frequency spectrum for arbitrary sample sizes
 - → extrapolation of vocabulary growth curve
 - or use population model directly as Bayesian prior etc.
